

The model Animals is responsible for declaring the animal class and storing the data on the specific animals.

It also inputs this data into the functions when they are called once an option is selected by the user.

The view SelectView is responsible for listening for a user input and taking that selected input and passing it on to the animals.js file so the information can be inputted from the class.

The populate method pulls in information from the subscription to all-animals-ready and goes through each animal and creates an array which is then used to populate the dropdown list.

The AnimalInfoView is responsible for taking the information inputted and creating the out put text that is to be displayed by the app.

The app.js calls the bindEvents functions from the other files so that the program all comes together and can be ran.
